ABSTRACT

Design of 3D seismic models has received much attention over the years, and yet relatively little has been presented regarding the optimization of these models for implementation by modern acquisition crews.

Our primary goal is to provide designs of sufficient technical merit to image the intended targets. However, along this path we are presented with many choices that give approximately equal imaging characteristics but bear great influence on the ultimate cost of the project.

Using the concept of cost densities, we offer some guidelines to project optimization.

The cost of acquisition of a 3D project can be greatly influenced by the arrangement of lines. We present demonstrations of optimizing layout to attain the most efficient patch rolling while minimizing utilization of recording equipment. We show how these considerations may be sensitive to survey shape and source type.

Today we are seeing the implementation of much larger 3D programs than ever before. We are often forced to “Zipper” our programs in order to record them with a practical amount of field equipment. We discuss several methods and considerations required to optimize this planning.

These aspects of project planning can result in cost variations from tens of thousands of dollars in smaller projects to millions of dollars in very large 3D's.

This is Submission Number is 438S0202

Efficiencies in 3D Design - Implementation and Operations

Norm Cooper
and Yajaira Herrera

1

- ✓ Equipment Demands
- ✓ Patch Movement
- ✓ “Zippered” Surveys
- ✓ Half-Patch Recording
- ✓ Variable Grids
- ✓ False Efficiencies

5

Line Spacing

$$SL \times RL = \frac{\pi \times \text{Offset}_{\text{Max}}^2}{4 \times \text{Desired Fold}}$$

Avoid: $SL / RL = 1.0$
 $SL / RL > 2.0$
 $SL / RL < 0.5$

6

The Fold Equation Assumes a Large Patch ...

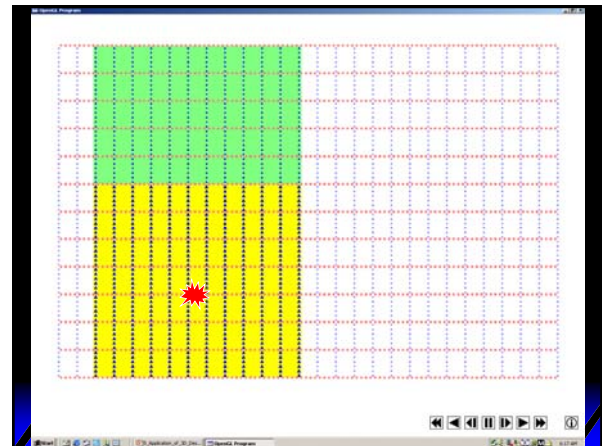

... Sufficient to record all useable offsets

7

Rolling the Patch - “Normal” roll

\\Demonstrations\RollDemo.exe

Rolling the Patch - “Vibroseis” roll

Demonstrations\RollDemo.exe

Rolling the Patch “Vibroseis” roll - Better

Demonstrations\RollDemo.exe

Patch Analysis

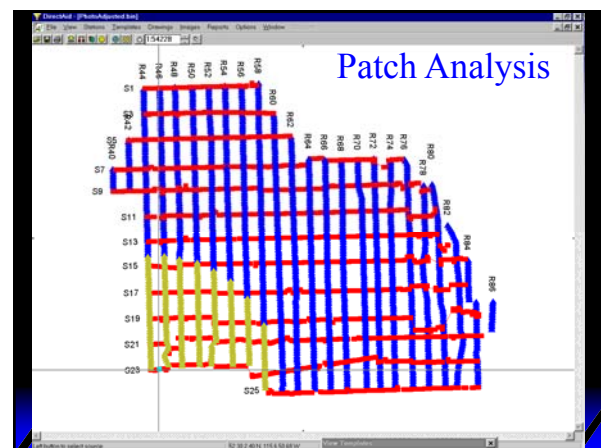

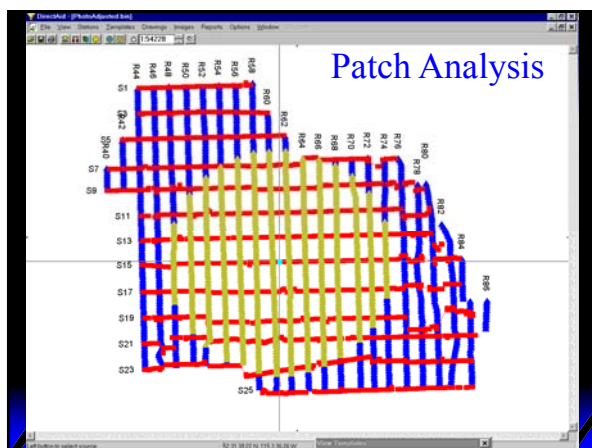

22

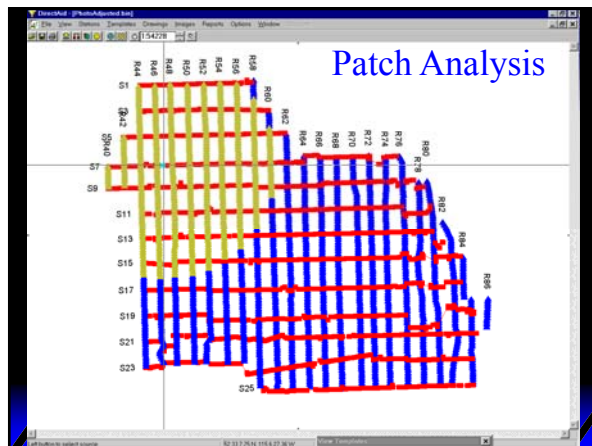

Sometimes, we are forced to use
Narrow Aperture Patches

... The patch width is not sufficient to record
all useable traces

Crossline
Channel
Summary

**“Half-Patch”
and “Ping-Pong”**

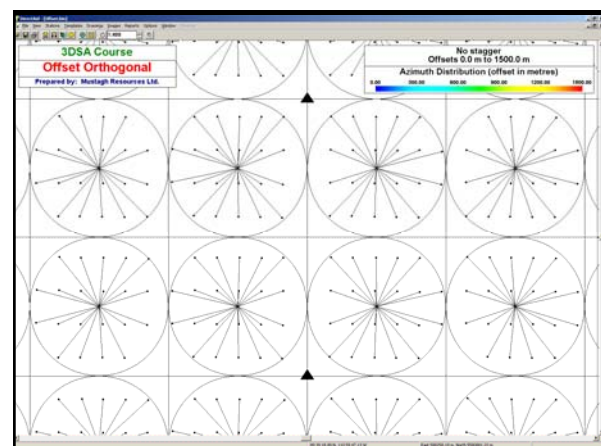

38

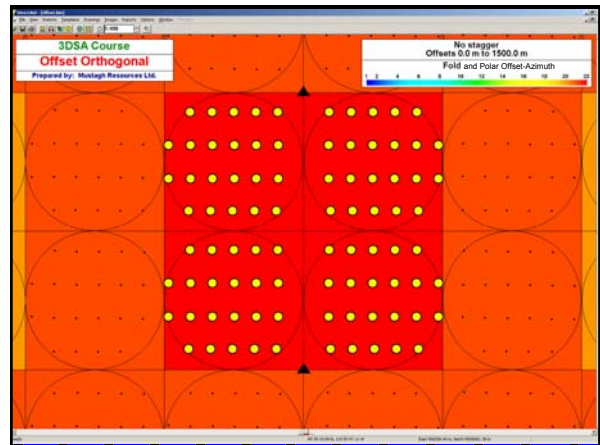

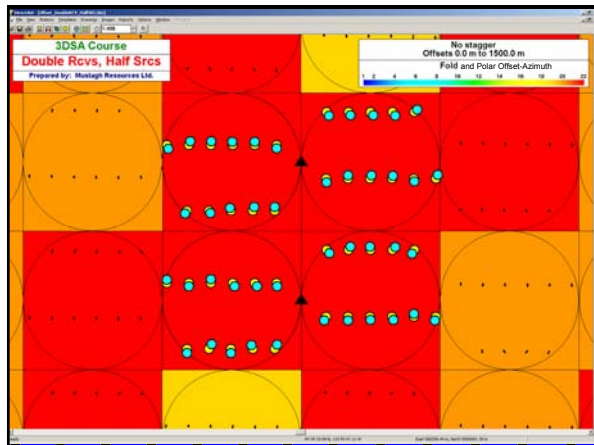

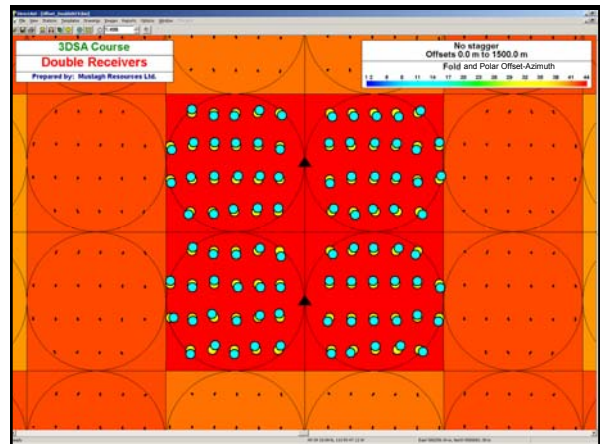

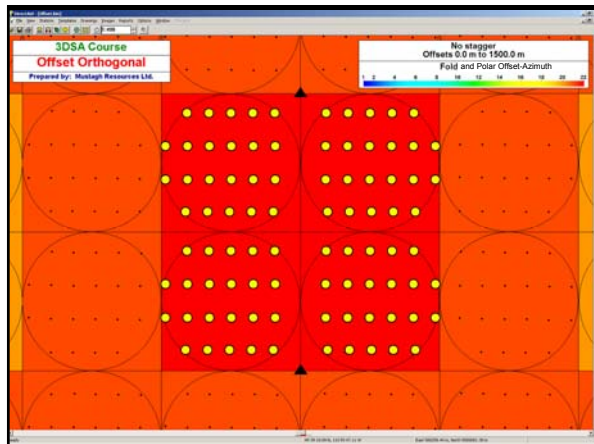

Variable Spacing Models

False Efficiencies

- ◆ Increase Fold by decreasing receiver interval and gathering in original bin size
- ◆ This generates non-diverse statistics within the over-sized bin as per the previous argument
- ◆ Fold is not our key consideration, **Sampling Diverse Statistics** within each bin is important

60

Cost Factors

Receiver line density	1.60	km per km ²
Source line density	1.08	km per km ²
Active patch lines 14		
Receiver line density	1.60	km per km ²
Source line density	1.08	km per km ²
Receiver point density	24.32	rcvs per km ²
Source point density	13.88	srcs per km ²
		approx. cost \$10,251 per km ²

61

Most Important Factors:

- Preservation of the Wavefield
 - bin size, patch size
- Statistical Diversity
 - grid density, aspect ratio
- Robustness under Perturbation
 - model type
 - skidding and offsetting

62

But Also :

- Minimize Costs
- Optimize Operational Efficiency
- Minimize Environmental Impact
